

Vojtěch Janoušek:

Interpretation of the whole-rock geochemical data using the R language

The challenge: interpretation of whole-rock chemical data

- Lunar program in the late 1960's came with the requirement of precise and accurate chemical, and then isotopic, analyses of small samples.
- In 1970's appeared novel analytical techniques for trace-element determinations (e.g., XRF; INAA), later ICP-OES, ICP-MS.
- Advancement of radiogenic isotope methods (originally TIMS, then SIMS, ICP-MS).

- Downside: the current flood of precise geochemical data needs to be interpreted by a potent and widely available software tool.

A revolution? The R Language

- Originally designed by Ihaka and Gentleman (1996)
- Version 1.0 published on 29 Feb 2000
- Based on syntax of the S language (Becker *et al.* 1988) which was developed at Bell Laboratories (formerly AT&T, now Lucent Technologies) by John Chambers and colleagues.

- The commercial version, S-PLUS, is currently being distributed by TIBCO Software (*www.tibco.com*)
- Since 1997 the development of the R project is overseen by an open group of experts, the R Development Core Team (*http://www.r-project.org*)
- R is Free Software distributed under the Free Software Foundation's GNU General Public License
- R is available for all main OS. It runs on a wide variety of UNIX platforms and similar systems (including FreeBSD and Linux), Windows and MacOS.

A revolution? The R Language

- Frequently updated, supported by a large and still growing community
- R is highly extensible by numerous additional packages
- Large collection of statistical (linear and nonlinear modelling, classical statistical tests, time-series analysis, classification, clustering, ...) and database tools
- Data import in many formats, also via SQL and ODBC
- Graphical facilities for data exploration and plotting
- High-level graphical output, well-designed publication-quality plots can include mathematical symbols and formulae where needed
- Graphics can be exported into many formats (*PostScript, WMF, PDF, TIFF, PNG...*), for incorporation into DTP programs, word processors or further editing
- Excellent control over individual functions [= power]
- R allows interactive as well as batch use (as a true programming language).
- Effective object-oriented programming language
- Most of the R system is written in R; for computationally intensive tasks, C, C++, and FORTRAN code can be linked and called at run time.

Geochemical Data Toolkit = GCDkit

http://www.gcdkit.org

MAIN FEATURES:

- A more human (less inhuman) interface to the wealth of functions in R
- Windows-like GUI = no programming necessary!!
- Data ready for further handling under R (dot prompt veterans)
- Standard geochemical calculations involving whole-rock major-, trace-element data and Sr-Nd isotopes
- Effective data management (searching, subsetting, grouping)
- Common plots (binary, ternary, spider, classification, geotectonic...)
- Publication quality graphic output

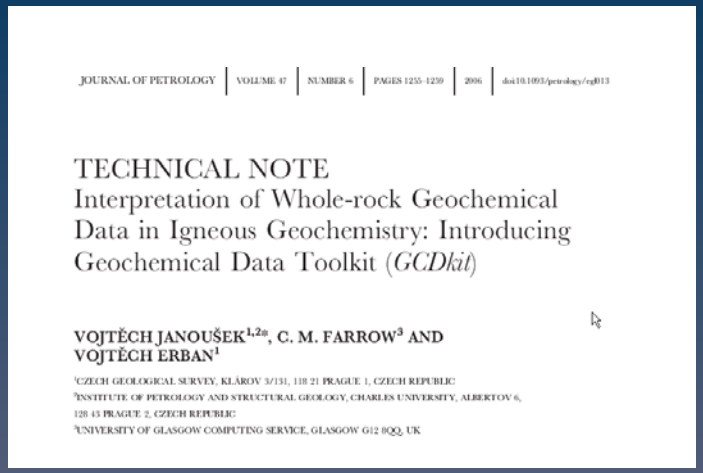
Main ‘milestones‘

- 2000 – launched graduate-level courses on interpretation of geochemical data using R (Masaryk University in Brno & Charles University in Prague)
- 2003 – Goldschmidt Conference, Kurashiki, Japan – *GCDkit* 1.0 released
- 2006 key publication in *Journal of Petrology* (141 hits on WOS)
- October 2015 – Monograph on Geochemical modelling in R/GCDkit (Springer Verlag)
- February 10, 2016 – last stable version (4.1, *Chlopskie jadlo*) released for current R (ver. 3.2.1)
- October 2016 – brand new graduate-level course on data analysis using R and Python (Charles University in Prague)



JOURNAL OF PETROLOGY | VOLUME 47 | NUMBER 6 | PAGES 1255–1259 | 2006 | doi:10.1093/petrology/egl013

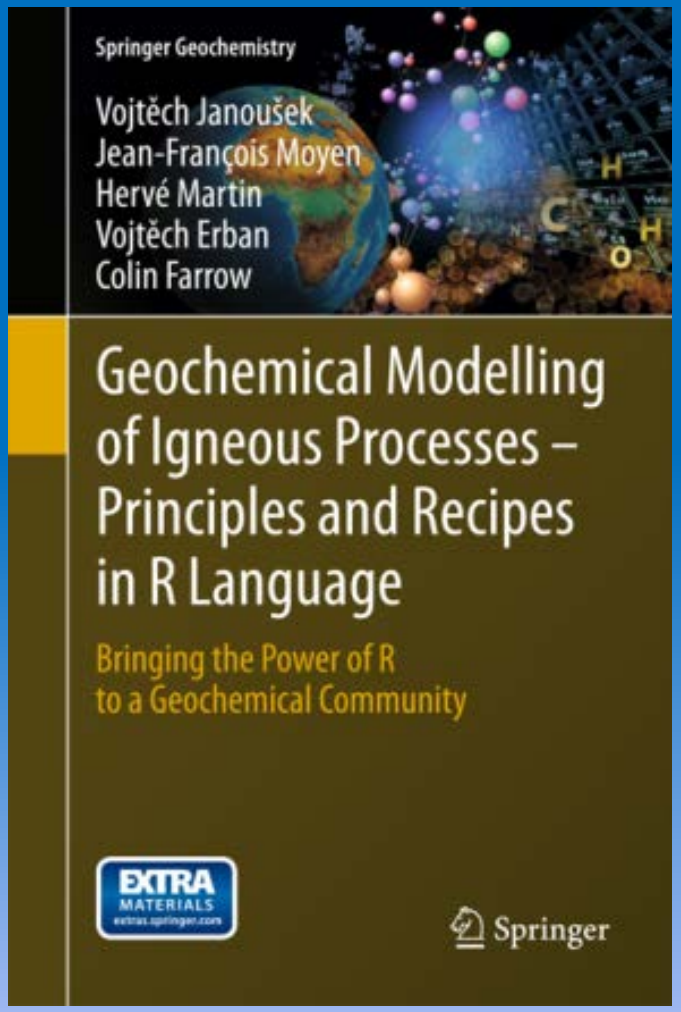
“The R Book” – philosophy



- Provides basics of R language and its application to geochemical problems,
- Gives the first comprehensive introduction to the *GCDkit* system,
- Explains fundamentals of numerical modelling of igneous processes,
- Shows not only formulae, but also the successful modelling strategies,
- Includes numerous worked examples how geochemical modelling helps us to understand geological problems.

Springer Geochemistry series, vol. 1

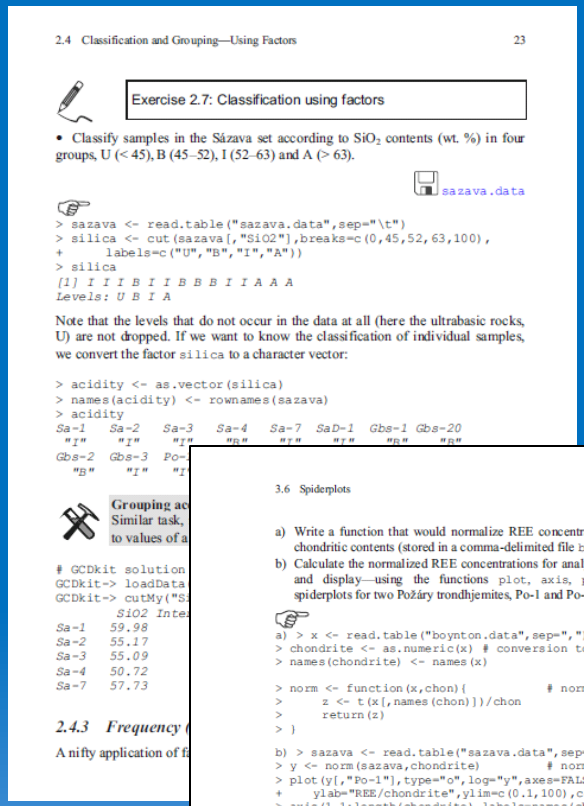
D 83,20 € | UK £72.00 | US $99.00

“The R Book” – contents

- **Part I: R/GCDkit at work**
  - Loading and manipulating data
  - Linking Whole-Rock Chemistry with Mineral Stoichiometry
  - Statistics
  - Classification and Grouping
  - Classical Plots (binary, Harker, ternary, spider)
  - Specialized Plots (log–log, specialized spiderplots, contour plots, anomaly plots…)
  - Radiogenic isotopes (initial ratios, epsilon values, model ages, isochrons…)



2.4 Classification and Grouping—Using Factors 23

Exercise 2.7: Classification using factors

- Classify samples in the Sázava set according to SiO_2 contents (wt. %) in four groups, U (< 45), B (45–52), I (52–63) and A (> 63).

sazava.data

```
> sazava <- read.table("sazava.data",sep="\t")
> silica <- cut(sazava[,"SiO2"],breaks=c(0,45,52,63,100),
+       labels=c("U","B","I","A"))
> silica
[1] I I I B I I B B B I I A A A
Levels: U B I A
```

Note that the levels that do not occur in the data at all (here the ultrabasic rocks, U) are not dropped. If we want to know the classification of individual samples, we convert the factor `silica` to a character vector:

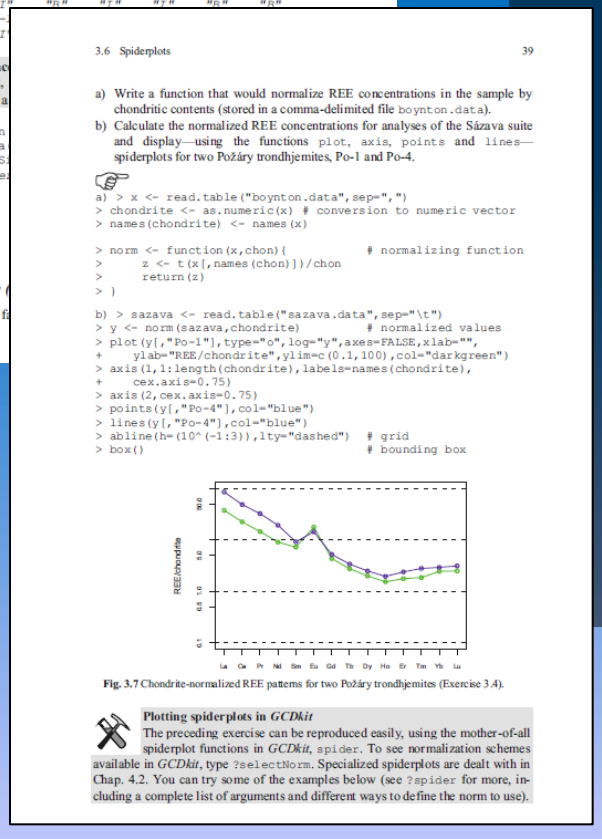
```
> acidity <- as.vector(silica)
> names(acidity) <- rownames(sazava)
> acidity
Sa-1  Sa-2  Sa-3  Sa-4  Sa-7  SaD-1  Gbs-1 Gbs-20
 "I"   "I"   "I"   "B"   "I"    "I"    "B"    "B"
Gbs-2 Gbs-3 Po-
 "B"   "I"  "I
```

Grouping ac
Similar task,
to values of a

```
# GCDkit solution
GCDkit-> loadData
GCDkit-> cutMy("Si
         SiO2 Inte
Sa-1    59.98
Sa-2    55.17
Sa-3    55.09
Sa-4    50.72
Sa-7    57.73
```

2.4.3 *Frequency*

A nifty application of f



3.6 Spiderplots 39

a) Write a function that would normalize REE concentrations in the sample by chondritic contents (stored in a comma-delimited file `boynton.data`).
b) Calculate the normalized REE concentrations for analyses of the Sázava suite and display—using the functions `plot`, `axis`, `points` and `lines`—spiderplots for two Požáry trondhjemites, Po-1 and Po-4.

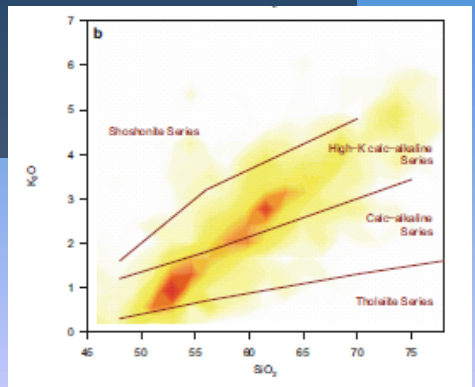
```
a) > x <- read.table("boynton.data",sep=",")
> chondrite <- as.numeric(x) # conversion to numeric vector
> names(chondrite) <- names(x)

> norm <- function(x,chon){                # normalizing function
>      z <- t(x[,names(chon)])/chon
>      return(z)
> }

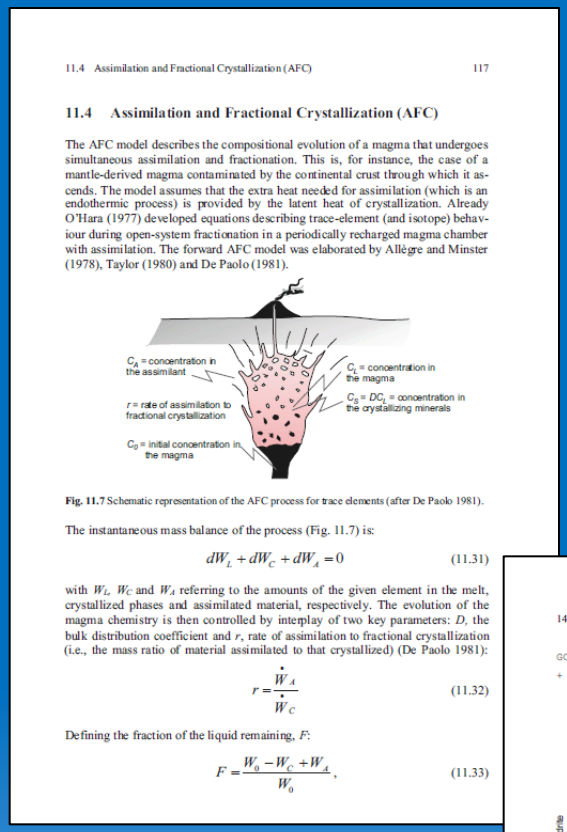
b) > sazava <- read.table("sazava.data",sep="\t")
> y <- norm(sazava,chondrite)              # normalized values
> plot(y[,"Po-1"],type="o",log="y",axes=FALSE,xlab="",
+    ylab="REE/chondrite",ylim=c(0.1,100),col="darkgreen")
> axis(1,1:length(chondrite),labels=names(chondrite),
+    cex.axis=0.75)
> axis(2,cex.axis=0.75)
> points(y[,"Po-4"],col="blue")
> lines(y[,"Po-4"],col="blue")
> abline(h=(10^(-1:3)),lty="dashed")   # grid
> box()                                # bounding box
```

Fig. 3.7 Chondrite-normalized REE patterns for two Požáry trondhjemites (Exercise 3.4).

Plotting spiderplots in *GCDkit*
The preceding exercise can be reproduced easily, using the mother-of-all spiderplot functions in *GCDkit*, `spider`. To see normalization schemes available in *GCDkit*, type `?selectNorm`. Specialized spiderplots are dealt with in Chap. 4.2. You can try some of the examples below (see `?spider` for more, including a complete list of arguments and different ways to define the norm to use).



“The R Book” – contents



11.4 Assimilation and Fractional Crystallization (AFC) 117

11.4 Assimilation and Fractional Crystallization (AFC)

The AFC model describes the compositional evolution of a magma that undergoes simultaneous assimilation and fractionation. This is, for instance, the case of a mantle-derived magma contaminated by the continental crust through which it ascends. The model assumes that the extra heat needed for assimilation (which is an endothermic process) is provided by the latent heat of crystallization. Already O'Hara (1977) developed equations describing trace-element (and isotope) behaviour during open-system fractionation in a periodically recharged magma chamber with assimilation. The forward AFC model was elaborated by Allègre and Minster (1978), Taylor (1980) and De Paolo (1981).

Fig. 11.7 Schematic representation of the AFC process for trace elements (after De Paolo 1981).

The instantaneous mass balance of the process (Fig. 11.7) is:

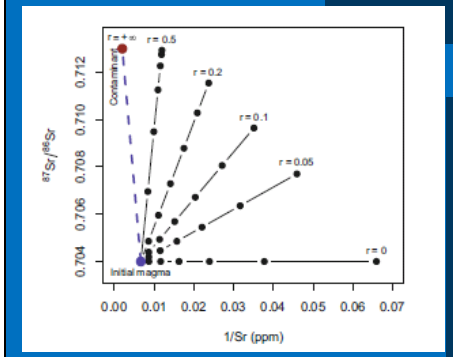
$$dW_L + dW_C + dW_A = 0 \qquad (11.31)$$

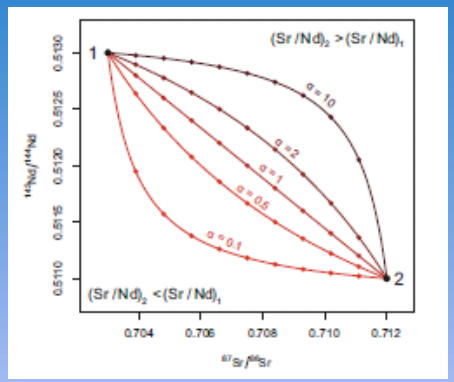
with W_L, W_C and W_A referring to the amounts of the given element in the melt, crystallized phases and assimilated material, respectively. The evolution of the magma chemistry is then controlled by interplay of two key parameters: D, the bulk distribution coefficient and r, rate of assimilation to fractional crystallization (i.e., the mass ratio of material assimilated to that crystallized) (De Paolo 1981):

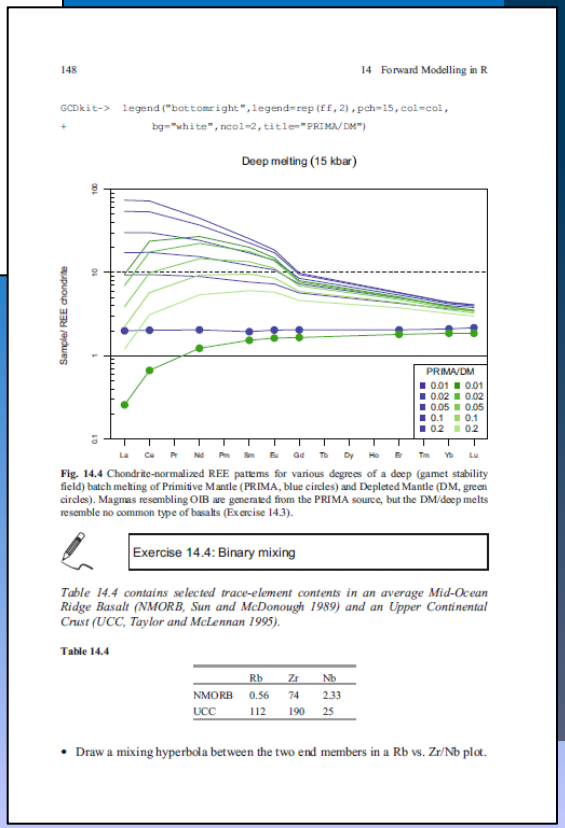
$$r = \frac{\dot{W}_A}{\dot{W}_C} \qquad (11.32)$$

Defining the fraction of the liquid remaining, F:

$$F = \frac{W_0 - W_C + W_A}{W_0}, \qquad (11.33)$$







148 14 Forward Modelling in R

```
GCDkit-> legend("bottomright",legend=rep(ff,2),pch=15,col=col,
+              bg="white",ncol=2,title="PRIMA/DM")
```

Deep melting (15 kbar)

Fig. 14.4 Chondrite-normalized REE patterns for various degrees of a deep (garnet stability field) batch melting of Primitive Mantle (PRIMA, blue circles) and Depleted Mantle (DM, green circles). Magmas resembling OIB are generated from the PRIMA source, but the DM/deep melts resemble no common type of basalts (Exercise 14.3).

Exercise 14.4: Binary mixing

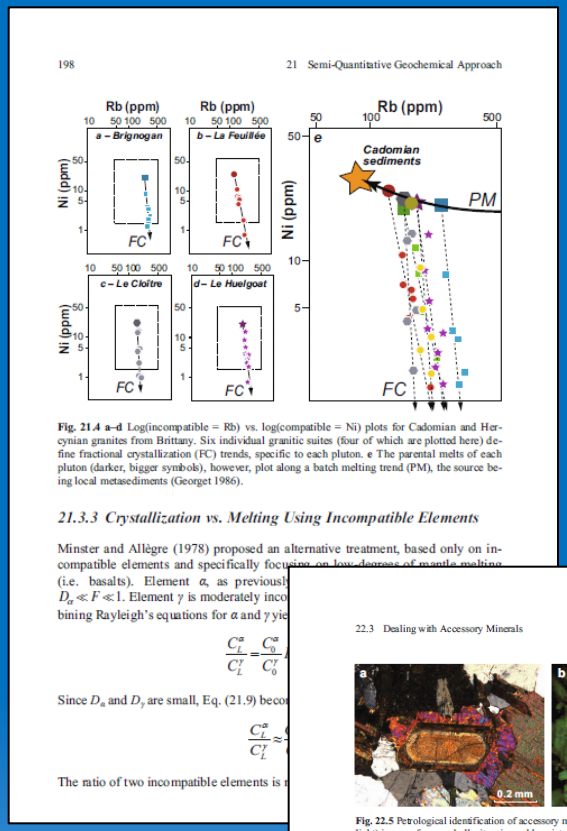
Table 14.4 contains selected trace-element contents in an average Mid-Ocean Ridge Basalt (NMORB, Sun and McDonough 1989) and an Upper Continental Crust (UCC, Taylor and McLennan 1995).

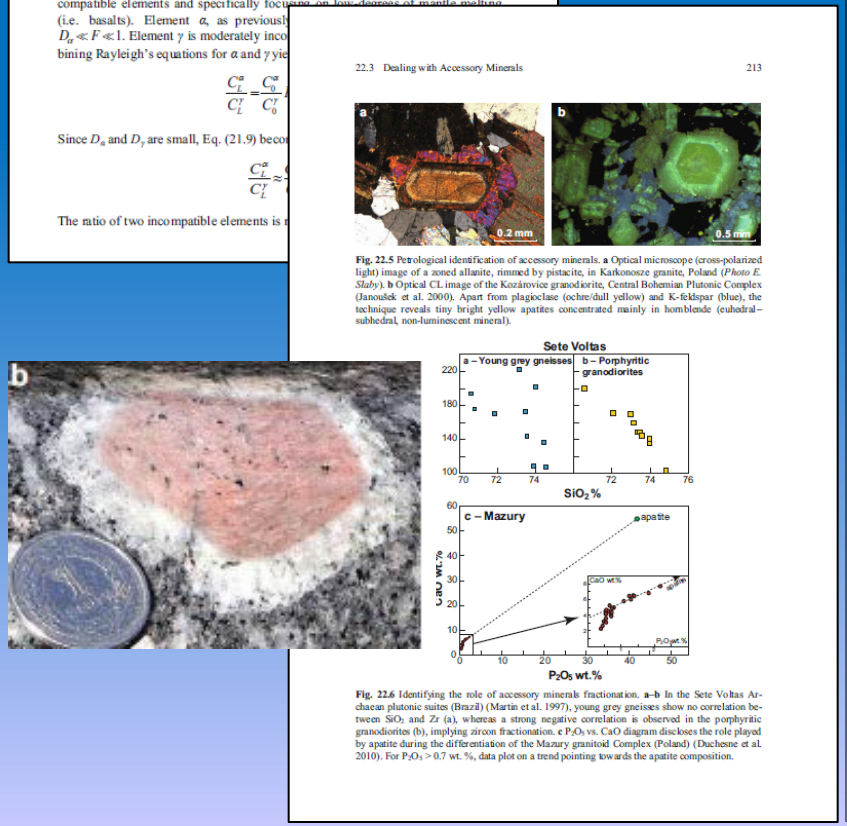
Table 14.4

	Rb	Zr	Nb
NMORB	0.56	74	2.33
UCC	112	190	25

- Draw a mixing hyperbola between the two end members in a Rb vs. Zr/Nb plot.

- **Parts II–IV: Majors, traces, radiogenic isotopes**
  - Core of the book
  - Explains fundamentals of each direct and reverse modelling, including the relevant formulae
  - Then introduces the numerical solution and its implementation in the R language
  - Includes a number of real numerical problems
  - Each is presented as a numerical receipt with solution in R (± *GCDkit*)





"The R Book" – contents

- **Part V: Practical Modelling**
- Choosing an Appropriate Model (evidence for crystallization, partial melting, magma mixing and assimilation…)
- Semi-Quantitative Approach (assessing the trace-element compatibility, process identification, mixing test…)
- Constraining a Model (using appropriate strategy, input parameters for the model, partition coefficients, dealing with accessories…)
- Numerical Tips and Tricks (reducing system, colinearity, breaking minerals to end-members, coupling majors and traces…)
- Common Sense in Action (thermodynamic, rheological constraints, scale/speed of processes, how well can we distinguish between models, dangerous projections…)

“The R Book” – contents

- **Part VI: Worked Examples**
  - Differentiation of a Calc-Alkaline Series: Atacazo-Ninahuilca volcanoes, Ecuador
  - Progressive Melting of a Metasedimentary Sequence: the Saint-Malo Migmatitic Complex, France
- Appendix A: R Syntax in a Nutshell
- Appendix B: Introduction to *GCDkit*

Chapter 26

Progressive Melting of a Metasedimentary Sequence: the Saint-Malo Migmatitic Complex, France[1]

26.1 Geological Setting

The Saint-Malo Massif belongs to the high-T belt of the Cadomian Orogen (Brun and Balé 1990). Figure 26.1 shows that it consists of three main lithological and metamorphic units (Brun and Martin 1977), which are, from S to N, (i) greenschist-facies micaschists and gneisses, (ii) amphibolite-facies gneisses, and (iii) migmatites. The metamorphic event, culminating in anatexis, has been dated at ca. 540 Ma (Peucat and Martin 1985; Peucat 1986).

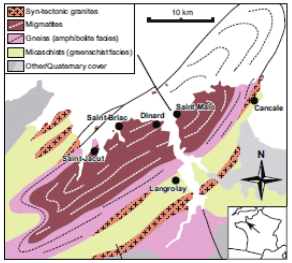

Fig. 26.1 Simplified geological map of the Saint-Malo Massif showing the geographical distribution of the main lithologies; the degree of metamorphism increases northwards, i.e. towards the core of the dome (redrawn after geological map of France and Martin 1980). Inset: sketch map of France for orientation; arrow shows the location of the Saint-Malo Massif.

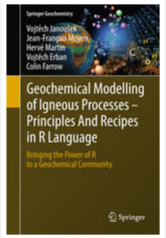
Book on geochemical modelling of magmatic processes in R/GCDkit

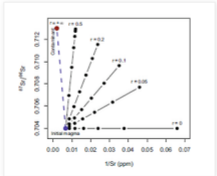
We break the two years of our silence with some news potentially interesting to anyone involved in interpretation of whole-rock geochemical data from igneous rocks. We are pleased to announce that, after two years of intense writing, we have finally published a book:



Janoušek, V., Moyen, J. F., Martin, H., Erban, V. & Farrow, C. M. (2016). *Geochemical Modelling of Igneous Processes – Principles and Recipes in R Language. Bringing the Power of R to a Geochemical Community*. Springer-Verlag, Berlin, Heidelberg, 346 pp.

doi:10.1007/978-3-662-46792-3

Abstract from the publisher:



"The aim of this book is to unlock the power of the freeware R language to advanced university students and researchers dealing with whole-rock geochemistry of (meta-) igneous rocks. The first part covers data input/output, calculation of commonly used indexes and plotting in R. The core of the book then focuses on the presentation and practical implementations of modelling techniques used for fingerprinting processes such as partial melting, fractional crystallization, binary mixing or AFC using major-, trace-element and radiogenic
